

THERMALISATION OF LONGITUDINAL GLUONS

Abstract

In the usual real-time finite-temperature gauge theory both the physical and the unphysical degrees of freedom are thermalised. We discuss the alternative approach where only the physical transverse components of the gauge field have bare thermal propagators, whereas the unphysical degrees of freedom are not heated. We show how pinch singularities are avoided: sometimes this requires resummation. If only the hard thermal loop is included in the resummation, the spatially-longitudinal component of the gauge field, which contains an extra collective plasmon mode, becomes fully thermalised, though the Faddeev-Popov ghost and the remaining unphysical component of the gauge field remain frozen.

March 1993

1. FREEZING THE UNPHYSICAL DEGREES OF FREEDOM

Finite-temperature field theory in the real-time formulation^[1] requires a doubling of fields into type 1 and type 2. All propagators are 2×2 -matrices and the information on the thermal distribution of particles resides in the matrices which diagonalise these propagators. A bosonic propagator has the form

$$\mathbf{D} = \mathbf{M} \tilde{\mathbf{D}} \mathbf{M}, \quad (1.1a)$$

with

$$\tilde{\mathbf{D}} = \begin{pmatrix} \Delta_F & 0 \\ 0 & -\Delta_F^* \end{pmatrix} \quad (1.1b)$$

and

$$\mathbf{M} = \sqrt{n(|K_0|)} \begin{pmatrix} e^{\beta|K_0|/2} & e^{(\sigma-\beta/2)K_0} \\ e^{(\beta/2-\sigma)K_0} & e^{\beta|K_0|/2} \end{pmatrix}, \quad (1.1c)$$

where $n(x) = 1/(e^{\beta x} - 1)$ is the Bose-Einstein distribution function with temperature $T = 1/\beta$. The constant σ , whose value has to be chosen to be between 0 and β , parametrises different versions of the real-time formalism.

In gauge theories, the usual approach^[2] is to treat physical and unphysical degrees of freedom on the same footing, which requires that also the Faddeev-Popov ghost fields are thermalised (i.e. have a propagator of the form (1.1)). In a previous work^[3] we have shown that, in the real-time formalism, it is possible and even simpler to thermalise only the physical transverse components of the gauge field. Thus only these components involve the matrix $\mathbf{M}$ of (1.1c), while the unphysical part of the gauge boson propagator and the Faddeev-Popov ghost propagator have the form (1.1a) but with the matrix

$$\mathbf{M}_0 = \begin{pmatrix} 1 & e^{\sigma K_0 \theta(-K_0)} \\ e^{-\sigma K_0 \theta(K_0)} & 1 \end{pmatrix} \quad (1.1d)$$

replacing $\mathbf{M}$. The value of σ defines the choice of the time path of the real-time formalism and so must be the same in both $\mathbf{M}$ and $\mathbf{M}_0$. One may choose σ to be some finite fraction of β , but it appears to be more natural to make the original choice of Keldysh, $\sigma = 0$. Then $\mathbf{M}_0$ is the zero-temperature limit of $\mathbf{M}$ and so the propagators of the unphysical fields are frozen:

$$\mathbf{M} = \sqrt{n(|K_0|)} \begin{pmatrix} e^{\beta|K_0|/2} & e^{-\beta K_0/2} \\ e^{\beta K_0/2} & e^{\beta|K_0|/2} \end{pmatrix} \quad \mathbf{M}_0 = \begin{pmatrix} 1 & \theta(-K_0) \\ \theta(K_0) & 1 \end{pmatrix}. \quad (1.1e)$$

We shall use this choice for the rest of this paper.

We adopt the metric $(1, -1, -1, -1)$ and write $K_\mu = (K_0, \mathbf{k})$, and $k_\mu = (0, \mathbf{k})$, so that $k.k = -\mathbf{k}^2$. If we introduce the spatially-transverse projection operator

$$A_{\mu\nu} = \delta_{\mu\nu} - \frac{k_\mu k_\nu}{k.k} \quad (1.2a)$$

with

$$\delta_{\mu\nu} = g_{\mu\nu} - g_{\mu 0} g_{\nu 0} \quad (1.2)$$

the gluon propagator in Feynman gauge takes the form

$$\mathbf{D}^{\mu\nu} = -A^{\mu\nu} \mathbf{M} \tilde{\mathbf{D}} \mathbf{M} - (g^{\mu\nu} - A^{\mu\nu}) \mathbf{M}_0 \tilde{\mathbf{D}} \mathbf{M}_0. \quad (1.3a)$$

In a general linear gauge with quadratic gauge breaking term $\frac{1}{2\xi}(A^\mu f_\mu f_\nu A^\nu)$, where f_μ is a 4-vector which is either constant or constructed from derivatives $\partial/\partial x$, one has to replace

$$g_{\mu\nu}\tilde{\mathbf{D}} \rightarrow \begin{pmatrix} G_{\mu\nu}\Delta_F & 0 \\ 0 & -G_{\mu\nu}^*\Delta_F^* \end{pmatrix} \quad (1.3b)$$

with

$$G_{\mu\nu}(k) = g_{\mu\nu} - \frac{k_\mu \tilde{f}_\nu + \tilde{f}_\mu k_\nu}{\tilde{f} \cdot k} + (\tilde{f}^2 - \xi k^2) \frac{k_\mu k_\nu}{(\tilde{f} \cdot k)^2}. \quad (1.3c)$$

In [3] we have demonstrated that this formalism simplifies perturbative calculations in general gauges, by showing that it reproduces the known results for the hard thermal part of the one-loop gluon self-energy and the two-loop interaction pressure and at the same time verifying explicitly their complete gauge independence.

However, the bare propagator (1.3a) leads to a potential difficulty at higher loop orders. Eventually thermal and nonthermal propagators carrying the same loop momentum are multiplied together by self-energy insertions, and the mismatch between the matrices $\mathbf{M}$ and $\mathbf{M}_0$ might give rise to pinch singularities^{[4][5]} which are absent in the conventional real-time formalism. In section 2 we shall inspect the form of these singularities in general; at least in physical quantities we expect them to cancel out, which we shall verify in the example of the 3-loop gluon interaction pressure in section 3.

In recent years it has become clear that perturbation theory of high-temperature QCD needs to be improved in order to be able to study physics at the energy scale $g^2 T$. For this, all effects appearing at the scale gT , which arise from the leading temperature contributions of one-loop diagrams (“hard thermal loops”)^[6], need to be resummed^[7]. In section 4 we shall consider in particular pinch singularities caused by the insertion of hard thermal loops into bare gluon propagators, finding that resummation of hard thermal loops remove these singularities in the full propagator.

In our formalism the bare propagator separates physical from unphysical modes, thermalising only the former. However, the contributions from the hard thermal loops give rise to a modified spectrum of a gluon plasma: the originally massless transverse gluons acquire (momentum-dependent) thermal masses. Moreover there is a new physical collective mode of *spatially longitudinal* gluons, the plasmon^{[6][8]}. This is possible because of the existence of a second projection operator which is transverse with respect to four dimensions, but spatially longitudinal,

$$B_{\mu\nu} = g_{\mu\nu} - \frac{K_\mu K_\nu}{K^2} - A_{\mu\nu}. \quad (1.4)$$

This raises the question whether the division between physical and unphysical modes in the full propagator can be as simple as in (1.3a). In fact we shall find in section 4 that resummation changes the division of the gluon propagator into thermal and nonthermal pieces. Indeed, the part of the longitudinal gluon propagator containing (1.4) also acquires a thermal structure, though the unphysical polarisations, which are longitudinal also with respect to 4 dimensions, remain at zero temperature.

In section 5, we summarise our findings and also comment on recently reported problems^[9] with covariant gauges in the resummation program of Braaten and Pisarski^[7].

2. PINCH SINGULARITIES AT TWO-LOOP ORDER

Consider loop corrections to the gauge-boson propagator (1.3). The bare propagator (1.3a) with (1.1e), corresponding to the Keldysh choice $\sigma = 0$ of the time path, satisfies

$$D^{11}(K) + D^{22}(K) = D^{12}(K) + D^{21}(K), \quad (2.1)$$

and so, from its definition, does the full propagator $\mathcal{D}^{ab}$. Consequently the self-energy correction

$$\Pi^{ab} = (D^{-1})^{ab} - (\mathcal{D}^{-1})^{ab} \quad (2.2)$$

obeys

$$\Pi^{11}(K) + \Pi^{12}(K) + \Pi^{21}(K) + \Pi^{22}(K) \equiv 0. \quad (2.3)$$

Furthermore we have $D^{11*} = -D^{22}$ and $D^{12}(K) = D^{21}(-K)$, which also is valid for the components of $\mathcal{D}$ and Π .

In this paper, we shall explicitly work in covariant gauges, though it is straightforward to extend to other gauges that preserve rotational invariance (with the heat bath at rest). In such gauges the tensor structure of the self-energy involves

$$C_{\mu\nu} = \frac{1}{|\mathbf{k}|} \left(g_{\mu 0} - \frac{K_\mu K_\nu}{K^2} \right) K_\nu + (\mu \leftrightarrow \nu), \quad D_{\mu\nu} = \frac{K_\mu K_\nu}{K^2}, \quad (2.4)$$

in addition to the tensors $A_{\mu\nu}$ and $B_{\mu\nu}$ introduced in (1.2a) and (1.4). $A_{\mu\nu}$ is orthogonal to the other three tensors, and all of them are mutually orthogonal under a trace.

At the one-loop level, the full propagator receives the contribution **D****II****D**. In a general covariant gauge, the non-thermal part of the bare propagator (1.3) has the tensor structure $G^{\mu\nu} - A^{\mu\nu} = B^{\mu\nu} + \xi D^{\mu\nu}$. Because this is orthogonal to $A^{\mu\nu}$, in the above product the thermal part of **D**, which involves **M**, decouples from the non-thermal part involving **M**₀. The term involving the thermal parts of the two **D**'s has the form

$$\begin{aligned} \mathbf{DIIID} &= \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} (n(-K_0)\Pi_a^{12} + n(K_0)\Pi_a^{21}) \Delta_F \Delta_F^* \\ &\quad + \Delta_F^2(\dots) + \Delta_F^{*2}(\dots), \end{aligned} \quad (2.5)$$

where the suffix a denotes the coefficient of $A_{\mu\nu}$ in the tensor decomposition of Π , and we have made use of the identity (2.3). The term involving the non-thermal part of **D** has a similar form, but with the zero-temperature limit $-\theta(\mp K_0)$ of the Bose distributions $n(\pm K_0)$.

The presence of a term proportional to $\Delta_F \Delta_F^*$ leads to an ill-defined singular expression, commonly called a pinch singularity [4], when it appears within a two-loop diagram and is integrated over K , unless its coefficient vanishes at $K^2 = 0$, the pole of Δ_F . Usually in the real-time formalism there is in addition to the trivial identity (2.3) a relation containing information on the thermal nature of the self-energy,

$$n(-K_0)\Pi^{12} + n(K_0)\Pi^{21} = 0 \quad (2.6)$$

which removes the pinch. But in our formalism some of the internal propagators in Π correspond to temperature β^{-1} and others to temperature 0, so that the identity (2.6) is not valid. If we define an effective (generally momentum-dependent) temperature associated with the self energy by

$$\beta_\Pi = \frac{1}{K_0} \ln \frac{\Pi^{21}}{\Pi^{12}} \quad (2.7)$$

then Π^{ab} may be diagonalised according to

$$\mathbf{\Pi} = \mathbf{M}_{\Pi}^{-1} \begin{pmatrix} \Pi & 0 \\ 0 & -\Pi^* \end{pmatrix} \mathbf{M}_{\Pi}^{-1}, \quad (2.8)$$

with $\mathbf{M}_{\Pi}$ as in (1.1c) but with $\beta = \beta_{\Pi}$, and the potential pinch singularity in (2.5) is determined by

$$\mathbf{D}\mathbf{\Pi}\mathbf{D} \Big|_{\Delta\Delta^*} = \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} 2i\epsilon(K_0) [n_{\Pi}(K_0) - n_D(K_0)] \text{Im } \Pi \quad (2.5')$$

($n_D(K_0)$ being either $n(K_0)$ or $-\theta(-K_0)$). So it is present unless $\text{Im } \Pi$ vanishes at $K^2 = 0$. Explicit calculations show that it does not vanish – in a high-temperature expansion there is a leading term proportional to $\theta(-K^2)T^2$; the subleading term is nonvanishing also for $K^2 > 0$ and even diverges logarithmically when $K^2 \rightarrow 0$. In [5] this problem has been discussed in the context of physical, nonthermalised constituents of a plasma interacting with thermalised ones.¹ With our treatment of unphysical degrees of freedom which keeps them at zero temperature, there is equally a potential problem with pinch singularities at ≥ 2 -loop orders.

Before addressing the problem of how to handle the ill-defined terms associated with pinch singularities in general, we shall verify the expectation that this problem should disappear for physical quantities by inspecting the gluon-interaction pressure. There pinch singularities potentially appear starting at the 3-loop order.

3. CANCELLATION OF PINCH SINGULARITIES IN THE 3-LOOP PRESSURE

In the calculation of the pressure at 3-loop order, the diagrams containing potential pinch singularities when calculated with the Feynman rules introduced in section 1 are shown in figure 1.² We recall that^[4] in each diagram at least one vertex should be of type 1.

The diagrams of figure 1a give rise to

$$\text{tr } \Pi^{1a} D^{ab} \Pi^{bc} D^{c1}, \quad (3.1)$$

where the trace is over the Lorentz indices and includes integration over the momentum argument. The thermal part of the bare gluon propagator is proportional to the spatially transverse projection operator $A_{\mu\nu}$. Because this is orthogonal to the other transverse projectors B, C and D which complete the tensor basis (see (1.4) and (2.4)), the thermal propagator times the self-energy is again proportional to $A_{\mu\nu}$. This is orthogonal to the nonthermal tensor structure in (1.3), hence there is no contribution when one gluon propagator is thermal and the other nonthermal.

With both propagators either thermal or nonthermal we find for the term proportional to $\Delta_F \Delta_F^*$ in (3.1)

$$\text{tr}(\text{Re } \Pi_{11} - i \tanh(\beta_{\Pi} K_0/2) \text{Im } \Pi_{11}) P (n_D(-K_0) \Pi_{12} + n_D(K_0) \Pi_{21}) P \Delta_F \Delta_F^*, \quad (3.2)$$

¹ We disagree with the analogous expressions given in [5] because there it was erroneously assumed that the nonthermal matrix $\mathbf{M}_0$, introduced in (1.1d), would be just the identity matrix. This does not however change any of the conclusions of [5].

² Because of the less singular behaviour of fermionic propagators, more than two would be required to have a chance of producing pinch singularities.

where for thermal propagators $n_D(x) = n(x)$, $P_{\mu\nu} = A_{\mu\nu}$, and for nonthermal ones $n_D(x) = -\theta(-x)$, $P_{\mu\nu} = G_{\mu\nu} - A_{\mu\nu}$. Considering two thermal propagators first, we find that the projection operators $A_{\mu\nu}$ make (3.2) proportional to $\text{Im } A^{\mu\nu}(K)\Pi_{\mu\nu}(K)$. This vanishes however at $K^2 = 0$, as we show in Appendix A. For the case of two nonthermal propagators we shall consider general covariant gauges, where $G_{\mu\nu}(K) = g_{\mu\nu} - (1 - \xi)K_\mu K_\nu / K^2$ in (1.3). We shall need the result, also proved in Appendix A, that

$$K^\mu \text{Im } \Pi_{\mu\nu} = O(K^2), \quad (3.3)$$

as well as

$$K^\mu K^\nu \Pi_{\mu\nu}^{ab} \equiv 0. \quad (3.4)$$

The simplest case is the term proportional to $(1 - \xi)^2$. This contribution vanishes identically by virtue of (3.4). For the other terms we introduce the abbreviations

$$\Pi_I(K) = \text{Im } \Pi(K), \quad \Pi' = \text{Re } \Pi_{11} - i \tanh(\beta_\Pi K_0/2) \text{Im } \Pi_{11} \quad (3.5)$$

(suppressing Lorentz indices). The term proportional to $(1 - \xi)$ has the structure

$$K^\mu \Pi_{I\mu\nu}(g - A)^{\nu\lambda} \Pi'_{\lambda\rho} K^\rho / K^2 \equiv K^\mu \Pi_{I\mu 0} \Pi'_{0\rho} K^\rho / \mathbf{k}^2, \quad (3.6)$$

because of (3.4), which then vanishes at $K^2 = 0$ by (3.3). Finally, the term corresponding to Feynman-gauge propagators is proportional to

$$\text{tr}(g - A) \Pi_I(g - A) \Pi' = \Pi_{I00} \frac{K^\mu K^\nu}{\mathbf{k}^2} \Pi'_{\mu\nu} + O(K^2), \quad (3.7)$$

upon using (3.3), which vanishes by (3.4).

The other diagram, figure 1b, has a potential pinch singularity proportional to the 1-2-component of the ghost self-energy. The part of the ghost-self energy containing the nonthermal part of the propagator is innocuous, because this fits to the nonthermal ghost propagators. The critical term arises from having the thermal part of the gauge propagator coupled to the ghost propagator. In covariant gauges, the latter has the form

$$\int d^4 Q K^\mu A_{\mu\nu}(Q) (K + Q)^\nu \delta((K + Q)^2) \delta(Q^2) \dots, \quad (3.8)$$

which, however, vanishes algebraically at $K^2 = 0$.

We have thus shown that the 3-loop contributions to the gluon interaction pressure are free from pinch singularities. Because the pressure is a physical quantity, this can be viewed as a further test of the consistency of the Feynman rules introduced in [3].

4. RESUMMATION OF PINCH SINGULARITIES

Pinch singularities make their appearance in off-shell Green's functions, for example in the 2-loop self-energy diagram obtained by opening one line of a 1-loop subdiagram in figure 1a. In this section we shall first restrict our attention to the leading temperature corrections of self-energy insertions, $\Pi \propto g^2 T^2$, the so-called hard thermal loop. When we calculate the latter in our formalism, we obtain exactly the same result as usually, of the form

$$\Pi_{\mu\nu}^{\text{HTL}} = \mathbf{M}^{-1} \left(\tilde{\Pi}_A A_{\mu\nu} + \tilde{\Pi}_B B_{\mu\nu} \right) \mathbf{M}^{-1}, \quad (4.1)$$

where $\mathbf{M}$ is the same matrix as in the spatially transverse piece of the bare propagator (1.3), and $\tilde{\Pi}$ is of a form analogous to (1.1b). Pinch singularities are caused by the second term in (4.1), because it does not match the matrix $\mathbf{M}_0$ in the nonthermal part of the bare propagator and because $\text{Im } \Pi_B$ does not vanish at $K^2 = 0$ if the light cone is approached from the spacelike side. These pinch singularities become worse at higher loop orders, i.e. the more self-energy graphs are inserted between bare propagators.

We shall now demonstrate that it is only the perturbative loop expansion which is ill-defined here, and that the problem disappears upon resummation of hard thermal loops. Resummation means that we have to invert $\mathcal{D}^{-1} = \mathbf{D}^{-1} - \Pi$. In our formalism the gluon propagator in a general covariant gauge reads

$$\mathbf{D}_{\mu\nu}^{-1} = -\mathbf{M}^{-1} A_{\mu\nu} \tilde{\mathbf{D}}^{-1} \mathbf{M}^{-1} - \mathbf{M}_0^{-1} \left(B_{\mu\nu} + \frac{1}{\xi} D_{\mu\nu} \right) \tilde{\mathbf{D}}^{-1} \mathbf{M}_0^{-1}. \quad (4.2)$$

(Strictly speaking, the tensors $B_{\mu\nu}$ and $D_{\mu\nu}$ have to be given a matrix form analogous to (1.1b), but for ease of presentation we shall pretend that they are real quantities.) The full inverse propagator can now be written as

$$\begin{aligned} \mathcal{D}^{-1} = & -\mathbf{M}^{-1} \left[A_{\mu\nu} (\tilde{\mathbf{D}}^{-1} + \tilde{\Pi}_A) + B_{\mu\nu} (\mathbf{M} \mathbf{M}_0^{-1} \tilde{\mathbf{D}}^{-1} \mathbf{M}_0^{-1} \mathbf{M} + \tilde{\Pi}_B) \right] \mathbf{M}^{-1} \\ & - \frac{1}{\xi} \mathbf{M}_0^{-1} \tilde{\mathbf{D}}^{-1} \mathbf{M}_0^{-1}. \end{aligned} \quad (4.3)$$

Inverting (4.3) simply means inverting the individual matrices appearing as coefficients of the tensors A , B , and D , where the interesting term is the spatially longitudinal one, proportional to $B_{\mu\nu}$. In momentum space the latter reads

$$\mathcal{D}_B^{-1} = \mathbf{M}^{-1} \begin{pmatrix} K^2 - \Pi_B + i\epsilon & 2i\epsilon e^{-\beta K_0} \theta(K_0) \\ 2i\epsilon e^{\beta K_0} \theta(-K_0) & -K^2 + \Pi_B^* + i\epsilon \end{pmatrix} \mathbf{M}^{-1}. \quad (4.4)$$

Inversion of this matrix, which for $K_0 > 0$ (< 0) is of upper (lower) triangular form with infinitesimal off-diagonal elements, yields

$$\mathcal{D}_B = \mathbf{M} \begin{pmatrix} \frac{1}{K^2 - \Pi_B + i\epsilon} & \frac{2i\epsilon e^{-\beta K_0} \theta(K_0)}{(K^2 - \Pi_B + i\epsilon)(K^2 - \Pi_B^* - i\epsilon)} \\ \frac{2i\epsilon e^{\beta K_0} \theta(-K_0)}{(K^2 - \Pi_B + i\epsilon)(K^2 - \Pi_B^* - i\epsilon)} & -\frac{1}{K^2 - \Pi_B^* - i\epsilon} \end{pmatrix} \mathbf{M}. \quad (4.5)$$

Evidently, the pinch singularities have disappeared in this resummed expression.

This implies that pinch singularities caused by hard thermal loop insertions in the bare propagator are just an artefact of the ordinary loop expansion. In order to check that this is also the case beyond the hard-thermal-loop level, we shall restrict ourselves to Landau gauge. In general, the self-energy contains also nontransverse terms proportional to $C_{\mu\nu}$ (the tensor $D_{\mu\nu}$ is excluded however by (A.1)) which in gauges other than Landau gauge spoil the simplicity of the above arguments, as seen from Appendix B; in Landau gauge such terms are projected out. The transverse part of the general self-energy is given by

$$\Pi = \mathbf{M}_A^{-1} A_{\mu\nu} \tilde{\Pi}_A \mathbf{M}_A^{-1} + \mathbf{M}_B^{-1} B_{\mu\nu} \tilde{\Pi}_B \mathbf{M}_B^{-1}, \quad (4.6)$$

where for general momentum the effective temperature associated with M_A or M_B , which is defined by (2.7), may be different from the physical one and from zero, depending on the gauge (which means that it does not have a direct physical interpretation). We therefore have

$$\begin{aligned} \mathcal{D}^{-1} = & -\mathbf{M}_A^{-1} \left[A_{\mu\nu}(\mathbf{M}_A \mathbf{M}^{-1} \tilde{\mathbf{D}}^{-1} \mathbf{M}^{-1} \mathbf{M}_A + \tilde{\boldsymbol{\Pi}}_A) \right] \mathbf{M}_A^{-1} \\ & - \mathbf{M}_B^{-1} \left[B_{\mu\nu}(\mathbf{M}_B \mathbf{M}_0^{-1} \tilde{\mathbf{D}}^{-1} \mathbf{M}_0^{-1} \mathbf{M}_B + \tilde{\boldsymbol{\Pi}}_B) \right] \mathbf{M}_B^{-1}, \end{aligned} \quad (4.7)$$

and again we find that the 2×2 -structure of the propagator is

$$\mathcal{D}_{A,B} = \mathbf{M}_{A,B} \begin{pmatrix} \frac{1}{K^2 - \Pi_{A,B} + i\epsilon} & O(\epsilon) \\ O(\epsilon) & -\frac{1}{K^2 - \Pi_{A,B}^* - i\epsilon} \end{pmatrix} \mathbf{M}_{A,B}. \quad (4.8)$$

Similarly, the Faddeev-Popov ghosts have to be resummed; only at the level of hard thermal loops there is no thermal contribution to the ghost self-energy so that ghosts remain completely nonthermal. From (4.8) we again conclude that while pinch singularities may arise at higher loop orders, they are not there in the full theory. They are removed by dressing the propagators.

5. DISCUSSION

We have found that upon resummation of hard thermal loops the originally nonthermal part of the gauge propagator containing spatially longitudinal polarisations acquires a thermal structure involving the usual matrix $\mathbf{M}$ given in (1.1e). This part of the propagator, eq. (4.5), can be regarded to be thermalised at the physical temperature for those momenta where one can neglect the off-diagonal terms in the central matrix on the right-hand side of (4.5). This is obviously the case when Π_B has an imaginary part, because then the explicit $i\epsilon$ in (4.5) can be put to zero. The hard-thermal-loop part of Π_B reads^[6]

$$\Pi_B = -K^2 \frac{m_{el.}^2}{\mathbf{k}^2} \left(1 - \frac{K_0}{2|\mathbf{k}|} \ln \frac{K_0 + |\mathbf{k}|}{K_0 - |\mathbf{k}|} \right) \equiv K^2 \pi_B, \quad (5.1)$$

where $m_{el.}^2 = g^2 N T^2 / 3$, and this has an imaginary part for space-like momenta, $K^2 < 0$. For $K^2 > 0$, new poles arise from $1/(1 - \pi_B)$ corresponding to extra collective (plasmon) modes, but for these the explicit $i\epsilon$ is superfluous, too, because in the full propagator these excitations have finite damping at the order $g^2 T$. It is thus essential to let $\epsilon \rightarrow 0$ before performing the high-temperature expansion and restricting to the hard-thermal loop (5.1), which is real for $K^2 > 0$. Therefore only at $K^2 = 0$, where Π_B vanishes, the $i\epsilon$ in (4.5) still seems necessary. With it, the explicit off-diagonal term in (4.5) reads

$$-\frac{2\pi i \delta(K^2) e^{-\beta K_0} \theta(K_0)}{(1 - \pi_B)(1 - \pi_B^*)}. \quad (5.2)$$

However, π_B diverges logarithmically at $K^2 = 0$ so that this vanishes unless it gets multiplied by some other factor that is singular at $K^2 = 0$. We expect that this will not happen, because the $K^2 = 0$ singularity of the resummed propagator is absent from the start in Coulomb gauge, see (B.7). Since we have found that the explicit off-diagonal terms in (4.5) can be neglected, we conclude that the resummation of hard thermal loops induces a complete thermalisation of the originally nonthermal spatially-longitudinal modes of the gluon. This is physically appealing

because it is associated with the appearance of extra collective modes which have no counterpart in the bare theory.

Moreover, we have found that the pinch singularities which seem to be caused by hard thermal loop insertions at higher loop orders are just a signal that the bare theory no longer is adequate, as they go away upon resummation. Hence, they are an artefact of the loop expansion.

In the conventional formalism, the need to resum hard thermal loops manifests itself by gauge dependences of one-loop results for plasma parameters at the energy scale g^2T , signalling incompleteness of the unimproved perturbation theory, whereas pinch singularities are automatically avoided. In our formalism the need to eliminate pinch singularities provides another indicator that resummation is needed to obtain complete results.

In fact, as concerns pure gauge modes, our formalism appears to be more suitable to deal with the problems recently encountered in treating covariant gauges at finite temperature. In the conventional formalism, even after resummation the pure gauge modes contained in the gauge boson propagator give rise to ambiguous terms in such supposedly physical quantities as damping rates of collective excitations. For example, the damping rate of fermionic excitations, extracted from the dressed fermion self-energy diagram, is found to be gauge dependent within the class of covariant gauges^[9], unless an explicit infra-red regularisation is retained to transform the singularity of the fermion propagator into a simple pole^[10]. This complication is due to thermalised unphysical massless modes which aggravate the infrared-behaviour of the fermion self-energy. In our formalism, which does not thermalise pure gauge modes, the latter remain nonthermal after resummation of the transverse hard thermal self-energies, so this problem is completely avoided. The resummed self-energy is still gauge dependent, however the leading terms of the imaginary part of order g^2T are determined by one-loop diagrams where all lines are thermal. As we have seen, in covariant gauges the gauge parameter dependent part of the propagator does not thermalise upon resummation so that the leading contributions to the resummed damping rates are manifestly gauge independent.

APPENDIX A:

TRANSVERSALITY AND TRACELESSNESS OF $\text{Im } \Pi(K^2 = 0)$

In this Appendix we give some details of the derivation of the results used in the text that the imaginary part of the one-loop self-energy of gluons in general covariant gauge is both transverse and traceless at $K^2 = 0$.

The complete self-energy is double transverse,

$$K^\mu K^\nu \Pi_{\mu\nu} \equiv 0 \quad (A.1)$$

as a consequence of BRS-invariance, but not necessarily transverse, $K^\mu \Pi_{\mu\nu} \neq 0$. Because of (A.1), tracelessness of $\text{Im } \Pi$ at $K^2 = 0$ implies

$$A^{\mu\nu} \text{Im } \Pi_{\mu\nu} \Big|_{K^2=0} = 0. \quad (A.2)$$

$\text{Im } \Pi_\mu^\mu = O(K^2)$ is most easily checked in Coulomb gauge. Potential gauge dependences appear in the part of the one-loop diagram containing both a thermal and a nonthermal propagator. Because of the form (1.3c), these contain a loop-momentum vector contracting with a bare 3-vertex, and using tree-level Ward identities one finds

$$\text{Im } \Pi_\mu^\mu(K) = \int d^4Q \delta(Q^2) \delta((K+Q)^2) (1-z^2) \dots, \quad z \equiv \frac{\mathbf{k}\mathbf{q}}{|\mathbf{k}||\mathbf{q}|}, \quad (A.3)$$

but $Q^2 = (K + Q)^2 = K^2 = 0$ implies $z^2 = 1$. Thus (A.2) holds for all linear gauges.

We now shall show

$$K^\mu \text{Im} \Pi_{\mu\nu} \Big|_{K^2=0} = 0, \quad \text{Im} \Pi_{\mu\nu} \propto \Pi_{\mu\nu}^{11}, \quad (\text{A.4})$$

in general covariant gauge. For the nonthermal part of $\Pi_{\mu\nu}$, transversality holds in general covariant gauges. We thus have to check those terms that contain at least one projector $A_{\mu\nu}$. They have the form

$$\begin{aligned} K^\mu \Pi_{\mu\nu}^{11} &= \int d^4 Q \delta(Q^2) \delta((K + Q)^2) [g^{\sigma\rho} Q^2 - Q^\sigma Q^\rho] A_\sigma^\alpha(k + q) V_{\alpha\rho\nu}(K + Q, -Q, -K) \dots \\ &= \int d^4 Q \delta(Q^2) \delta((K + Q)^2) Q^\sigma A_\sigma^\alpha(k + q) [g_{\alpha\nu} K^2 - K_\alpha K_\nu] \dots, \end{aligned} \quad (\text{A.5})$$

where terms with two projectors $A_{\mu\nu}$ as well as terms proportional to $(1 - \xi)$ have cancelled. At $K^2 = 0$ only the last term in (A.5) is kept, which however is found to equal the integrand in (A.3), hence, vanishes.

APPENDIX B: RESUMMATION OF HARD THERMAL LOOPS IN GENERAL GAUGES

In general gauges that only respect rotational invariance in the rest frame of the heat bath, the full inverse propagator (4.3) can be written as

$$\begin{aligned} \mathcal{D}^{-1} &= -\mathbf{M}^{-1} \left[A_{\mu\nu} \left(\tilde{\mathbf{D}}^{-1} + \tilde{\mathbf{\Pi}}_A \right) + B_{\mu\nu} \left(\mathbf{M} \mathbf{M}_0^{-1} \tilde{\mathbf{D}}^{-1} (1 - g^2) \mathbf{M}_0^{-1} \mathbf{M} + \tilde{\mathbf{\Pi}}_B \right) \right] \mathbf{M}^{-1} \\ &\quad - \mathbf{M}_0^{-1} \left[C_{\mu\nu} f g \tilde{\mathbf{D}}^{-1} + D_{\mu\nu} f^2 \tilde{\mathbf{D}}^{-1} \right] \mathbf{M}_0^{-1}, \end{aligned} \quad (\text{B.1})$$

where f and g parametrise the possible gauge choices, with $f \neq 0$.

The matrices A , B , C , and D , which were introduced above, fulfil

$$\begin{aligned} A.B &= B.A = A.C = C.A = A.D = D.A = 0, & A + B + D &= \mathbf{1}, \\ A.A &= A, & B.B &= B, & C.C &= -(B + D), & D.D &= D, \\ (B + D).C &= B.C + C.B = C.D + D.C = C. \end{aligned} \quad (\text{B.2})$$

With these relations one can show that the inverse of a matrix

$$\mathbf{X}_{\mu\nu} = \mathbf{a} A_{\mu\nu} + \mathbf{b} B_{\mu\nu} + \mathbf{c} C_{\mu\nu} + \mathbf{d} D_{\mu\nu}, \quad (\text{B.3})$$

if it exists and if it has an analogous decomposition

$$\mathbf{X}_{\mu\nu}^{-1} = \bar{\mathbf{a}} A_{\mu\nu} + \bar{\mathbf{b}} B_{\mu\nu} + \bar{\mathbf{c}} C_{\mu\nu} + \bar{\mathbf{d}} D_{\mu\nu}, \quad (\text{B.4})$$

is given by

$$\begin{aligned} \bar{\mathbf{a}} &= \mathbf{a}^{-1}, & \bar{\mathbf{b}} &= (\mathbf{b} + \mathbf{c} \mathbf{d}^{-1} \mathbf{c})^{-1}, \\ \bar{\mathbf{c}} &= -\mathbf{d}^{-1} \mathbf{c} \bar{\mathbf{b}}, & \bar{\mathbf{d}} &= \mathbf{d}^{-1} - (\mathbf{d}^{-1} \mathbf{c})^2 \bar{\mathbf{b}}. \end{aligned} \quad (\text{B.5})$$

(The existence of (B.4) imposes the following conditions on the commutators of the matrices in (B.3): $[\mathbf{b}, \mathbf{d}^{-1} \mathbf{c}] = 0$ and $[\mathbf{d}, \mathbf{c} \mathbf{d}^{-1} \mathbf{c}] = 0$. This is trivially fulfilled by (B.1), because there $\mathbf{c} \propto \mathbf{d}$.)

Applying these formulae to (B.1), we find that the full propagator resumming the hard thermal loop contributions possesses the same terms proportional to $A_{\mu\nu}$ and $B_{\mu\nu}$, whereas additional parts with the same thermal structure as obtained in (4.5) arise, which can be combined with the $B_{\mu\nu}$ -piece in one tensor

$$B_{\mu\nu} - \frac{g}{f} C_{\mu\nu} - \frac{g^2}{f^2} D_{\mu\nu}. \quad (B.6)$$

The only part remaining nonthermal is $-f^{-2} \mathbf{M}_0 D_{\mu\nu} \tilde{\mathbf{D}} \mathbf{M}_0$, which vanishes in a homogeneous gauge, where one would scale $f, g \rightarrow \infty$. In strict Coulomb gauge we have $g/f = K_0/|\mathbf{k}|$, and (B.6) becomes

$$-\frac{K^2}{\mathbf{k}^2} g_{\mu 0} g_{\nu 0} \quad (B.7).$$

In this gauge there are no thermalised Faddeev-Popov ghosts already in the conventional formalism. We thus end up with the same resummed quantities as usually in Coulomb gauge^[7].
